1. Monitoring effectiveness

Appendix A.1 shows a breakdown of the effectiveness of the monitoring effort and the overall result is, as usual, very impressive. The VMRG visited 1151 Malleefowl mounds during the 2011/12 breeding season (all 'sought and found', plus all 'new' mounds), including 32 newly listed mounds found incidentally at four sites (5 mounds at v08, v15, v20, v23), following searches at two sites (6 mounds at v28 and v29), and at three new sites where we visited mounds that were known to land holders/managers (v25, v38, v39). Monitoring was completed earlier than ever before, with the last sites being completed in mid January.

A total of seven regular mounds were not found during the 2011 season (Appendix A.2) and these were scattered through four sites: most were not searched for and appear to have been forgotten. None of these mounds had been recorded as having been active in the past.

Overall, we managed to find 99.4% of the mounds that we set out to monitor (excluding the 32 newly added mounds).

Optional mounds, those that are on the 5 year list, were also well represented considering there was no obligation to inspect them this year; we visited these mounds last year and don't have to revisit again until 2015. Monitors inspected 30 of the 80 mounds that have been on the list for at least a year: none were active, but then you don't know for sure unless you look! Although optional (5yr) mounds don't have to be inspected every year, every bit of data helps so please d visit these mounds if you have the time and inclination. We also added 24 mounds in 11 sites to the optional list (all of which were visited in 2011), and added all mounds in three sites (v10, v17 and v22) that have not shown any evidence of Malleefowl breeding for many years (see below).

Five site searches were undertaken in 2011. Parts of established monitoring sites at Wedderburn (v29) and Skinners Flat (v31) were searched May 2011, and Nurcoung (v28) in both may and August, and several mounds were found and monitored later in the season. The Broughtons site (v36) in the heart of the Little Desert was increased in size by a 100 ha extension to the north (5 new mounds), and a new site was searched on the southern edge of the Little Desert. Unfortunately (and somewhat puzzling) not one Malleefowl mound was found over several hundred hectares of apparently suitable habitat. The site is less than 10km from Nurcoung, and while we didn't expect to find as many mounds as there are in Nurcoung, the complete absence of mounds was a surprise and indicates that Malleefowl have not bred within this site for many decades, if ever: this clearly indicates that the habitat is unsuitable for Malleefowl and probably always has been. While this was a disappointing result for those of us who toiled through the scrub, it's nonetheless a good result in that our understanding has been challenged, and such challenges provide opportunities to learn what really matters to Malleefowl.

Finally, on 1st March 2012, we searched a 100ha block that will soon be partly cleared by the Iluka sand mine just east of Bronzewing. We found 4 good mounds (and 3 other dubious structures), all of which were used in the past 5 years but none this season. While it was sad to think the habitat would soon be cleared, the unfortunate fact is that the prognosis for the birds in this block was very poor due to the history of illegal clearing that has occurred on the property and generally unsympathetic management. We hope that management will be more sympathetic after Iluka have revegetated the site. Iluka staff will use the findings of the search to monitor

Malleefowl in the block and devise a management strategy for any birds that might occur there.

Many groups helped us search these sites, including the Wedderburn Conservation Management Network, Parks Victoria (Inglewood), the Swan Hill Indigenous Work Crew, Greening Australia (Wimmera), the Natimuk Community, SES (Nhill), BOCA (Nhill), CVA (Horsham), and Iluka environmental staff. It is only by having experienced VMRG members participating in searches that we are able to make use of inexperienced volunteers, so a special thankyou to VMRG members who participated in the searches.

Demoting of mounds in v10, v17 and v22 to Optional status

Three sites in the south eastern Sunset block have been demoted to optional status, meaning that we will no longer be under pressure to visit all the mounds in these sites by the end of December each year. These sites are still important, and we still need to monitor them, but the circumstances at each of these sites are such that the timing is less important than at other monitoring sites.

V10 (1 Tree Plain BNT) and v17 (One Tree Plain) were both burnt in 1996 and have shown no signs of Malleefowl since then (although a single Malleefowl print was recorded in v17 last year). The mounds known in these sites have badly degraded over the past 15 years and are mostly inconspicuous and not nearly as attractive to Malleefowl as they once were.

Nonetheless, monitoring is important in these sites, although our target is a little different from usual. While there is currently no evidence that Malleefowl regularly occur in these sites at the moment, let alone breed, at 15 years post fire we can expect that Malleefowl will be returning to breed soon. When they do, we will see an increase in the number of Malleefowl prints in the sites, and probably at the known mounds. But the birds may not renovate the known mounds at these sites because after being burnt and neglected for 15yrs many are overgrown and so eroded that they are barely recognisable as mounds.

Thus, detecting Malleefowl prints will be our first indication that Malleefowl have returned and when we monitor these sites and walk from mound to mound, we should be especially vigilant in keeping an eye out for Malleefowl prints.

The shift of emphasis from counting active mounds to detecting prints at these sites also has consequences regarding the timing of the monitoring. While we try hard to complete the monitoring between October and December in order to make our breeding counts most accurate and comparable, this timeframe is less relevant for detecting prints. Indeed, the best time to detect the presence of Malleefowl in these sites is probably during autumn when the weather is generally milder and prints persist on the ground longer, and when Malleefowl are likely to spend more time wandering in search of food. If any of the mounds in these sites were active in the preceding spring/summer, we will know about it even if its many months later, because any changes in the condition of the severely degraded mounds will be very conspicuous.

It is for these reasons that we have marked all the mounds in v10, v17 and v22 as optional during the monitoring season. Rather than compete with other sites during the busy October to December period, we can be more flexible about when we

monitor these specific sites, and this is reflected in their change of status. However, it would be a mistake to consider these sites as unimportant! We still need to make an effort to monitor these sites; it's just that the timeframes are less particular.

2. Malleefowl Breeding numbers

Rainfall was extremely high across the mallee at the start of the year, causing major flooding in some areas, but late autumn and winter were drier than usual in many areas (Figure 1). Nonetheless, Malleefowl breeding seemed undeterred in most areas, possibly because soil moisture was high through much of the first half of the year due to the early downpours, providing an abundance of herbaceous foods until July/August when more typical rainfall conditions returned in time to wet the mound litter for breeding.

Of the 1151 mounds that were monitored in 2011/12, 158 were active (142 of these were inside our regular sites, 11 were mounds outside the strict site boundaries; and 5 were within the new sites v25, v38 and v39; see Appendix A 3a-c). This is a great result and, if we exclude the 5 active mounds in the new sites, is on par with the record set in 2008/9 when 151 mounds were active (143 inside sites).

Despite the generally excellent breeding numbers across the state (Figure 2, 3), there were some areas where breeding numbers slipped. For example, at Menzies (v14) only 5 active mounds were recorded, the lowest breeding number since 1997, and breeding numbers were also unusually low at nearby O'Bree's (v27). These results, and average or below average results from other sites in the North-east, caused a general downturn in breeding numbers in the North-east (Figure 4; see Appendix 2 for individual site trends).

Elsewhere across the state results were more favourable. In the Eastern Big Desert, breeding numbers have improved compared with the last couple of years, but are still lower than numbers in the 1990s. Although breeding numbers at Lowan (v20) (where we traditionally conduct our training each year) are still inexplicably low, breeding numbers at neighbouring Dattuck (v01) have increased this season. The Paradise site which is also nearby has also shown increases over the past few years, although this site is not included in the collective totals in Figure 4 as the site has only been monitored for 5 years.

But it was in the north west of the state (Murray-Sunset and Hattah; Figure 4) where the greatest increases have occurred over the past few years. Breeding numbers have soared since the long western Victorian drought ended, and are currently higher than they were in 1996 after which they declined precipitously. Its been a long wait for breeding numbers in the north-west to return to what they once were, but this only increased the joyous excitement of the volunteers who discovered that Malleefowl at their sites were back in business and 'pumping'!

In the Little Desert and the Wychitella areas, we don't really have enough data to look at long term trends. In the shorter term, there are positive signs from the Little Desert area where breeding numbers appear stable over the past few years, and very encouraging news from Kiata, the original Malleefowl 'sanctuary' in the LD, where breeding Malleefowl have returned after an absence of over a decade (although Malleefowl footprints were occasionally recorded over this period). In the Wychitella area, only two active mounds were recorded in 2011 compared with 3-4 in the three previous seasons. Whether this is something to be concerned about, or just a temporary blip, will become apparent over the next couple of season's monitoring.

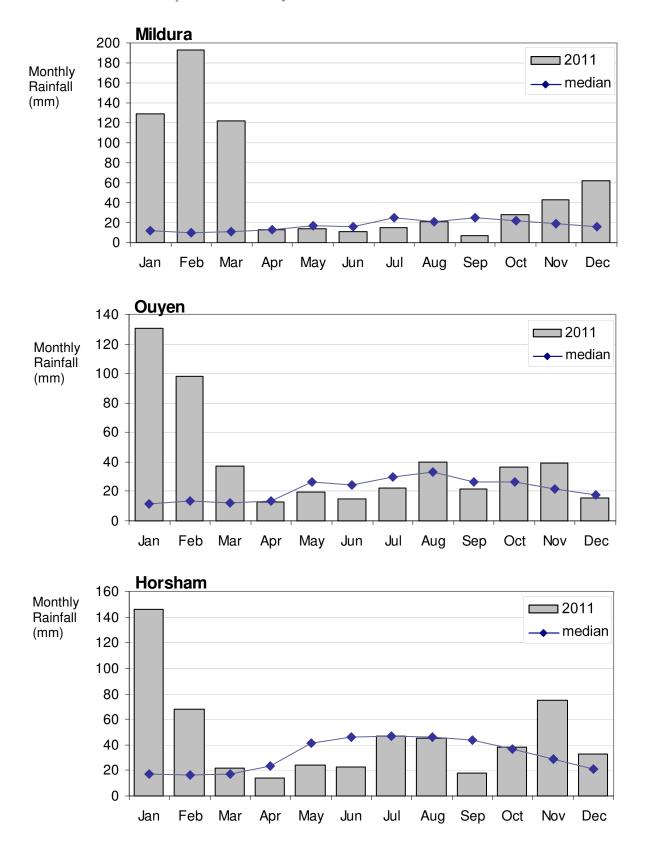

Figure 1. Rainfall at Mildura, Ouyen and Horsham in 2011 (bars) and median rainfall since early 1900s (line). Huge summer rainfall events affected all areas, while April to September totals were generally below the long term median. (Data from the Bureau of Meteorology website).

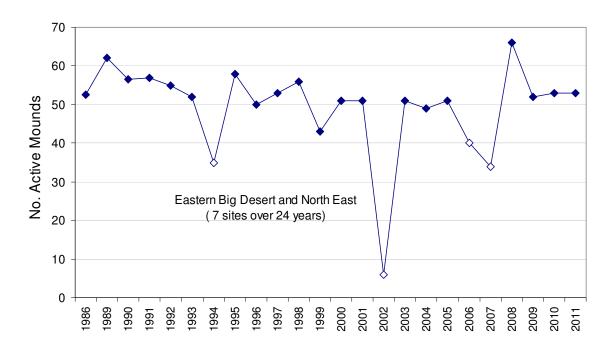

Figure 2. Trends in Malleefowl breeding numbers at 7 of the longest monitored sites over the past 24 years. 1994, 2002, 2006 and 2007 were major drought years (white points). Data comprise mounds in set areas across years in sites 01, 02, 03, 04, 07, 20 and 23.

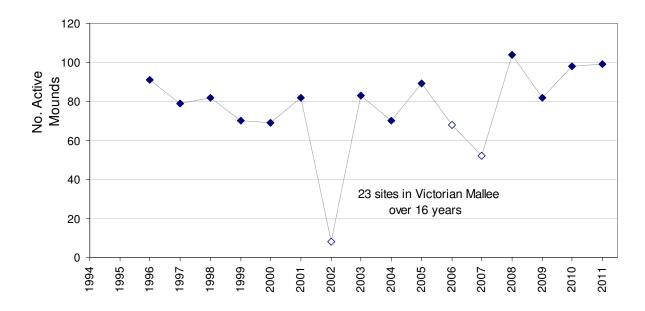

Figure 3. Trends in Malleefowl breeding numbers at 23 sites over the past 16 years shown as collective total. 1994, 2002, 2006 and 2007 were major drought years (white points). Data excludes mounds outside site boundaries. See figure 4 for regional breakdown.

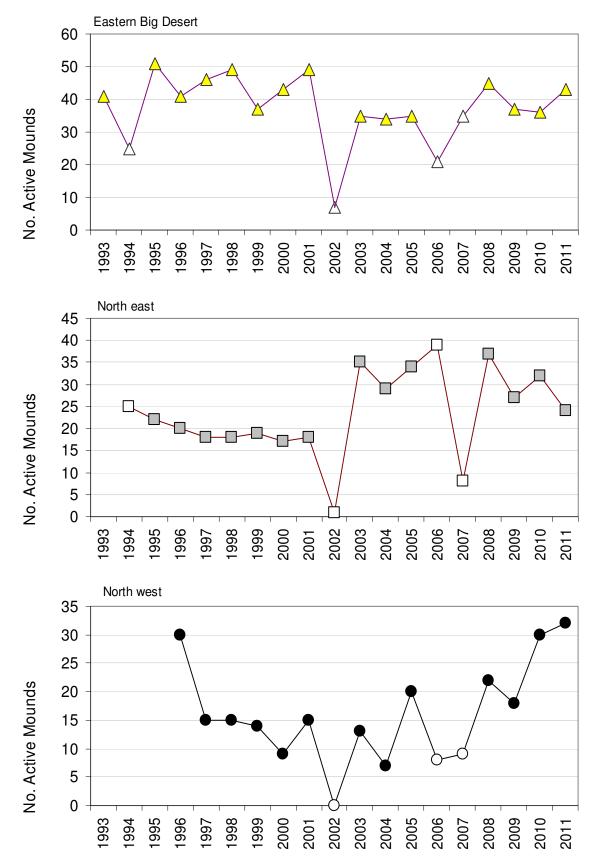

Figure 4. Trends in Malleefowl breeding numbers at 22 sites over the past 16-19 years shown by region. Eastern Big Desert comprise 6 sites over 19 years (triangles), North East comprise 4 sites over 18 years (shaded squares), and North West comprises 12 sites over 16 years (solid circles). 1994, 2002, 2006 and 2007 were major drought years in many areas. Data excludes mounds outside site boundaries.

Individual Site trends

Appendix B shows the histograms of grid trends from historical records to 2011/12. For each site, the bar graph displays the number of active mounds within the same area across years. The value (i.e. number of active nests) for each histogram bar is also shown so that you can distinguish between seasons when there was no breeding at a site, and seasons when the site was not monitored. Sites are represented in numerical order.

3. Changes to data recorded in the field

There were some changes to the Cybertracker sequence this season, although most of these changes would not be apparent to users (i.e. they were "under the hood"). One obvious change you might have noticed, even used, is a facility to record the number of hours spent travelling and monitoring a site. Keeping track of these data helps us report the effort volunteers make in monitoring Malleefowl, and in turn this helps us attract funds to keep the program going. So please make an effort to provide these details to us, either by using the Cybertracker page ("Log Hours" on the "DoWhat" screen) or some other means.

Another change is the ability to record deer, wombat and pig (!) prints and scats at mounds. While deer and wombats are mostly of interest in southern SA and relatively benign, pig signs have been increasing in the north eastern mallee in Victoria and are of great concern to Malleefowl conservation. We will be monitoring any signs of pigs near mounds and these data will be available to Parks Victoria and the mallee CMA for follow-up where required.

The Mobilemappers performed well for the majority of people and there were few problems. If you did experience problems, please bring these to the Mobilemapper training session at the training weekend.

4. Lerp

This season was the sixth time we have recorded the occurrence of lerp (the sweet and nutritious casing of psillid sap-sucking insects that fall from leaves) on Malleefowl mounds, but there were very few to count. Lerp were recorded at about 3% of mounds in 2011 (Appendix A VIII), compared to only 4% last season and 1% in 2009/10.

5. Fox scats

Fox scats were collected at 453 mounds in 2011/12 and weighed a total of 7.9 kg. This is much more than last year when there were 363 mounds with fox scats which weighed a total of 5.1 kg (Table 1), but we suspected that the tally last year may have been affected by the heavy summer rainfall that may have washed scats off mounds or hastened their disintegration. Figure 5 shows the average weight of fox scats collected per mound since the mid 1990s for the same set of 20 sites and provides a comparison across years. There are a few comments and qualifications to make regarding this graph. Firstly, it's apparent that more fox scats are collected during droughts, possibly because foxes are more territorial and hungrier when times are hard. This effect may also have increased fox scats on mounds in 1996 as rabbit populations plummeted after the spread of Rabbit Haemorrhagic Disease (RHD) Secondly, there was a steep decline in fox scat weights between 1996 and 2000 which coincides with, and probably reflects, the decline of rabbits due to RHD and

consequent adjustments to fox populations. Finally, there is a clear and increasing trend over the past decade suggesting that fox numbers are on the rise again, a trend certainly supported by anecdotal reports from various sources in the mallee. In fact fox scat weights for these sites are approaching levels not seen for 15 years.

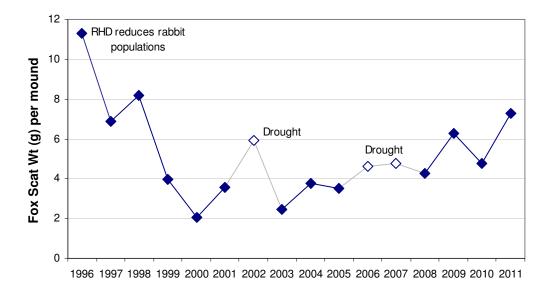

Figure 5. Trends in the average fox scat weight per mound at 20 sites over 16 years. No attempt has been made to control for biases due to variations in the proportion of active mounds (more likely to be marked with fox scats) or changes in the proportion of very old and inconspicuous mounds (less likely to be marked by foxes); values and patterns might change if these biases were considered (especially comparisons over large timeframes)..

Our measures of fox activity (% mounds with scats, and scat weights) in general agree with each other and provide valuable data on fox abundance trends which is a very difficult thing to measure in the field. Our measures are incidental to the monitoring of Malleefowl and are vulnerable to a number of biases (such as the variability in scat detection between observers); the measures are not perfect but they are simple and time efficient, and provide other valuable information on fox diet as well (thanks to Peter Sandell's efforts). Foxes are such an important and controversial factor in Malleefowl conservation that we do need to consider other routine methods of estimating trends in fox populations...but would volunteers be willing to make the extra effort?

Which brings us, as always, to reiterate:

May we remind everyone once again of the importance of being very systematic with fox scat collection. We must search the mound surface very carefully for a full minute to be to absolutely sure that we get all the scats, as emphasised in the manual and during the training weekends.

6. Concluding comments

Once again the VMRG has completed an excellent year of monitoring, and our results provide cause for optimism that Malleefowl are generally doing well ... at least for the time being.

However the many threats that the species faces have not gone away, and the prognosis for the species in the medium to longer term remains a concern. The great rains over the past four years have been associated with a rebound in Malleefowl breeding populations in many areas, but these conditions have been caused by la Nina events that are waning and provide only a temporary reprieve. If climate change progresses as expected we can expect climatic shifts that are deleterious to Malleefowl, especially if, as predicted, winters become drier. Fox numbers appear to be increasing and we are still unsure whether this is a major concern or not for Malleefowl conservation. The threat from fire has also increased over the past few years, due to Government policy rather than natural events, and it is difficult to see exactly where such policy will eventually lead. And while there are some laudable visions to reduce the degree of fragmentation of the mallee, changes on the ground are slow and we are still a long way from reducing this threat in a meaningful way except in a few small areas.

In this regard, the success of the Malleefowl Adaptive Management (AM) project (involving the VMRG, Parks Victoria and University of Melbourne) in attracting funding from the ARC has been a great and timely achievement. The AM project, under the leadership of Dr Michael Bode (you may have been lucky enough to hear him speak at the Malleefowl Forum in Renmark last year) will be funded for the next three years and will be tackling the crucial issue of how to make best use of the ongoing flow of monitoring data to better manage Malleefowl (see last year's report, and a paper in the Renmark Malleefowl forum for more details). We will be working closely with Michael and an expert team that includes Drs Libby Rumpff and Brendan Wintle (University of Melbourne) and Dr John Wright (Parks Victoria) to ensure the best possible program is in place and operational by the end of the project.

The AM project is an exciting development for Malleefowl conservation, and for the VMRG, and is in many ways a culmination of all our past effort to develop and implement a monitoring program for Malleefowl conservation. While the monitoring will continue much as it always has, there will also be some improvements, and new opportunities to gather information that is needed for the project. We hope the VMRG will be as responsive as they always have been to these new challenges and opportunities.

Joe Benshemesh and Peter Stokie March 2012

NOTE: If you notice any likely errors in this report or the Appendices, or numbers that disagree with your recollections, please let us know!

Table 1. The total weight of fox scats, the number of mounds at which fox scats were collected, for both 2010 and the previous year (italics). The number of mounds at which Malleefowl scats were collected is also shown. Feathers were also collected in 2011 and sent to Taneal Cope, but numbers have not been tabulated.

15	266	y	у		@FN=5 year @ECOLCOM=2011 request for 5yr listing approve given measures, photos and history
15	269	y	у		@FN=5 year @ECOLCOM=2011 request for 5yr listing approve given measures, photos and history
15	270	y	у		@FN=5 year @ECOLCOM=2011 request for 5yr listing approve given measures, photos and history
18	17	у	y		@CordCom:From notes: n17 is very hard to detect, this mm record was used at a false location and then reentered at correct location. (pjs) @ECOLCOM=2011 added to 5yr list after seeing photos and due to problems picking mound in field even when stake found!
30	3	у	у		@FN=prba ly not a nest
30	4	у	у		@FN=not a nest. needs to be delete @ECOLCOM=2011: psando asked for this to be deleted. photos show this was inconspicuous before fire but very nothing now. Moved to 5yr list and may delete entirely next time
31	19	y	у		 @FN=very very old and question if a mound. looks oblong. 5 yr li @ECOLCOM=2011 added to 5yr list on request of monitor and a timber covered and derelict
32	1	у	у		@FN=measurements same as previously . tree fallen over nesr see photo. suggest vist every 5 years. remote and difficult track with many large fallen trees across track. @ECOLCOM=loc off and can't be sure of id from photos but seems likely. Added to 5yr list request from monitor due to it being a long way from other monitored mounds and is thus inconvenient: it represents a lot of effort for little return. Suggest it is regularly monitored once the surrounding area is searched.

Appendix A 3c. 2011/12 Active Nests List

Page 2 of 2 Malleefowl Monitoring Database

+ Mounds that have been newly added to the monitoring program

Where sites have been divided into various parts, these are indicated to the right of the mound code (e.g. A, B, C, and 'oog' (out grid)). At Wandown (v15) site parts have been further subdivided into burnt ("b") and unburnt sections ("u").
